

**Problem 1.** An SCC graph  $G^{\text{scc}}$  of  $G$  is defined as follows:

- Each vertex in  $G^{\text{scc}}$  is a distinct SCC in  $G$ .
- For every two distinct SCCs  $S_i$  and  $S_j$  in  $G$ ,  $G^{\text{scc}}$  has an edge from  $S_i$  to  $S_j$  if some vertex of  $S_i$  has an edge in  $G$  to some vertex of  $S_j$ .

Prove:  $G^{\text{scc}}$  is a DAG (directed acyclic graph).

**Proof.** Let  $G = (V, E)$ . Suppose that  $G^{\text{scc}}$  contains a cycle  $C = S_0 - S_1 - \dots - S_k$  where  $S_k = S_0$ . Hence,  $(S_{i-1}, S_i) \in E^{\text{scc}}, \forall 1 \leq i \leq k$ , meaning that  $\exists s_{i-1} \in S_{i-1}, t_i \in S_i$  such that  $(s_{i-1}, t_i) \in E$ . Additionally, there is a path from  $t_i$  to  $s_i$  in  $G$  for all  $1 \leq i \leq k$ , by the definition of SCC that any two vertices in the same SCC are mutually reachable. Hence, any two vertices  $u, v$  satisfying  $u \in S_i, v \in S_j$  where  $1 \leq i, j \leq k$  are mutually reachable. This violates the definition that each vertex in  $G^{\text{scc}}$  is a distinct SCC.  $\square$

**Problem 2.** Let  $G = (V, E)$  be a directed simple graph stored in the adjacency-list format. Define  $G^{\text{rev}} = (V, E^{\text{rev}})$  to be the reverse graph of  $G$ , namely,  $E^{\text{rev}} = \{(v, u) | (u, v) \in E\}$ . Design an algorithm to produce the adjacency list of  $G^{\text{rev}}$  in  $O(|V| + |E|)$  time. You can assume that  $V = \{1, 2, \dots, n\}$ .

**Solution.** First, create an empty list  $L(u)$  for each vertex  $u \in V$ , and initialize an array  $A$  of size  $|V|$  where  $A[u]$  stores the head pointer to  $L(u)$ . For each vertex  $u \in V$ , the adjacency list of  $G$  stores the out-neighbours of  $u$  in a linked list, which are all the edges in  $G$ . Scan the linked list, and for each out-neighbour  $v$  of  $u$ , we add  $u$  to  $L(v)$ , indicating the edge from  $v$  to  $u$ .

**Problem 3.** Implement the SCC algorithm in  $O(|V| + |E|)$  time. You can assume that  $V = \{1, 2, \dots, n\}$ .

**Solution.** Perform DFS on the input graph  $G = (V, E)$  in  $O(|V| + |E|)$  time. Create a time stamp variable  $t$  for the number of vertices already popped. Let  $A$  be a list recording the order of vertices that turned black. Then, when  $v$  is being popped, then increment  $t$  and set  $A[t] = v$ .

The reversed graph  $G^{\text{rev}}$  can be obtained in  $O(|V| + |E|)$  time.

Scan through  $A$  from the last index, if  $A[i]$  is not yet visited, then start the DFS from vertex  $A[i]$ , this discovers a connected component. Repeat this process until the scan through  $A$  is completed.

**Problem 4.** Let  $G = (V, E)$  be a DAG, where each vertex  $u \in V$  carries an integer weight denoted as  $w_u$ . Let  $R(u)$  be the set of vertices in  $G$  that  $u$  can reach (i.e., for each vertex  $v \in R(u)$ ,  $G$  has a path from  $u$  to  $v$ ); note that  $u \in R(u)$  (i.e., a node can reach itself). Define  $W(u) = \min_{u \in R(u)} w_u$ . Design an algorithm to compute the  $W(u)$  values of all  $u \in V$  in  $O(|V| + |E|)$  time. (Hint: dynamic programming).

**Solution.** For every  $v \in V$ , let  $S(v)$  be the set of outneighbours of  $v$ . Then,

$$R(v) = \left( \bigcup_{u \in S(v)} R(u) \right) \cup \{v\}, W(v) = \begin{cases} \min \left\{ \min_{u \in S(v)} W(u), w_v \right\}, & \text{if } S(v) \neq \emptyset, \\ w_v, & \text{otherwise.} \end{cases}$$

Compute the topological order of  $G$  in  $O(|V| + |E|)$  time. Following the reversed topological order, all  $W(u)$ 's for  $u \in S(v)$  have been computed before computing  $W(v)$ . Only  $O(|S(v)|)$  time is needed to obtain the minimum. Hence,  $W(u)$  can be computed in  $O(|V| + \sum_v |S(v)|) = O(V + E)$  time as required.

**Problem 5.** Let  $G = (V, E)$  be an arbitrary directed simple graph, where each vertex  $u \in V$  carries an integer weight denoted as  $w_u$ . Let  $R(u)$  be the set of vertices in  $G$  that  $u$  can reach; note that  $u \in R(u)$ . Define  $W(u) = \min_{u \in R(u)} w_u$ . Design an algorithm to compute the  $W(u)$  values of all  $u \in V$  in  $O(|V| + |E|)$  time.

**Solution.** Consider two vertices  $u, v$  that belong to the same SCC and thus  $u$  and  $v$  are mutually reachable. This guarantees that any point reachable from  $u$  is reachable from  $v$ , and vice versa, implying that  $R(u) = R(v)$ . Obtain  $G^{\text{scc}}$  in  $O(|V| + |E|)$  time. For each SCC vertex  $S_i$ , reassign a weight by taking the minimum over all weights that are originally assigned to any vertex in  $S_i$ , i.e.  $\min_{v \in S_i} w_v$ . Let  $R(S_i)$  be the set of vertices in  $G^{\text{scc}}$  that  $S_i$  can reach and define  $W(S) = \min_{T \in R(S_i)} w_T$ . Then, we can compute  $W(S)$  in  $O(|V| + |E|)$  time by dynamic programming. Additionally, for any  $u$ ,  $W(u)$  is exactly  $W(S)$  where  $S$  is the SCC containing  $u$ .

**Problem 6.** Prove: all the SCCs of a directed simple graph are mutually disjoint.

**Proof.** Suppose the otherwise that there exists a pair of non-disjoint SCCs. Let  $S_1$  and  $S_2$  be the pair, where  $S_1 \cap S_2 \neq \emptyset$ . Suppose that  $e \in S_1 \cap S_2$ , then consider any  $e_1 \in S_1 \setminus S_2, e_2 \in S_2 \setminus S_1$ . Clearly,  $e$  and  $e_1$  are mutually reachable,  $e$  and  $e_2$  are also mutually reachable. Hence,  $e_1$  can reach  $e_2$  by stumbling onto  $e$  and follow the path where  $e$  can reach  $e_2$ . The same applies to  $e_2$ . Hence,  $e_1$  and  $e_2$  are mutually reachable, meaning that  $e_1, e_2 \in S_1 \cap S_2$ , which is a contradiction.  $\square$

**Problem 7.** Let  $G = (V, E)$  be a directed simple graph and  $G^{\text{scc}}$  be the SCC graph of  $G$ . Let  $S_1$  and  $S_2$  be two SCCs of  $G$ . Prove: if  $S_1$  cannot reach  $S_2$  in  $G^{\text{scc}}$ , then no vertex of  $S_1$  can reach any vertex of  $S_2$  in  $G$ .

**Proof.** Suppose the otherwise that some vertex of  $S_1, u$ , is able to reach a vertex of  $S_2, v$ , in  $G$ . Then, consider the path  $u - u_1 - \dots - u_k - v$ . Clearly, if two nodes belongs to the different SCCs  $S_i$  and  $S_j$ , then there is an edge from  $S_i$  to  $S_j$  in  $G^{\text{scc}}$  by the definition of SCC graph. Hence, a walk is constructed, starting from  $S_1$  and ends at  $S_2$  in  $G^{\text{scc}}$ , which is a contradiction.  $\square$

**Problem 8.** Prove:  $G$  and  $G^{\text{rev}}$  have the same SCCs.

**Proof.** Consider any two vertices  $u, v$  in the same SCC  $S$  on the original graph  $G$  by the paths  $P_1, P_2$ , one from  $u$  to  $v$ , the other from  $v$  to  $u$ . Hence, in the reversed graph  $G^{\text{rev}}$ , we can go from  $v$  to  $u$  through the edges of  $P_1$  (since they are reversed in  $G^{\text{rev}}$ ), and similarly, from  $u$  to  $v$  by  $P_2$ . Hence,  $u$  and  $v$  belong to the same SCC in  $G^{\text{rev}}$ . Let the SCC which  $u, v$  belong to in  $G^{\text{rev}}$  be  $S'$ , then  $S \subseteq S'$ .

Interchanging  $G^{\text{rev}}$  and apply the above argument implies that  $S' \subseteq S$  and hence  $S = S'$ , which is the desired.  $\square$

**Problem 9.** Prove: if an SCC  $S_1$  has a path to an SCC  $S_2$  in  $G^{\text{scc}}$ , then  $\text{label}(S_1) > \text{label}(S_2)$ .

**Proof.** Let  $u$  be the first vertex in  $S_i \cup S_j$  that turns gray in DFS.

If  $u \in S_i$ ,  $u$  has a white path to every vertex in  $S_i \cup S_j$ . By the white path theorem,  $u$  turns black after all the vertices in  $S_j$  and is the last vertex in  $S_i$  turning black. This implies  $\text{label}(S_i) > \text{label}(S_j)$ .

If  $u \in S_j$ ,  $u$  has a white path to every vertex in  $S_j$  but no white path to any vertex in  $S_i$ . By the white path theorem,  $u$  turns black after all the vertices in  $S_j$  and before every vertex in  $S_i$ . This again implies  $\text{label}(S_i) > \text{label}(S_j)$ .  $\square$

**Problem 10.** Prof. Goofy proposes his own SCC algorithm:

- Step 1: Perform DFS on the input graph  $G$  and compute a label for each vertex.
- Step 2: Perform another DFS on  $G$  subject to the following rules:
  - Start the first DFS from the vertex with the smallest label;
  - Whenever a restart is needed, do so from the white vertex with the smallest label.

Give a counterexample to this algorithm.

**Solution.**

For this input, vertex 1, 2, 3, 4 has label 4, 3, 2, 1, respectively. Hence, the algorithm marks 1, 2, 3, 4 together as one SCC, while each vertex is a disjoint SCC in itself.
